Nodular granulomatous episcleritis (NGE)

What Nodular granulomatous episcleritis (NGE)?

Nodular granulomatous episcleritis (NGE) is an immune-mediated (inflammatory) disease that affects the sclera, cornea and nictitating membrane. The condition is diagnosed most commonly in Collies, Cocker Spaniels, and related breeds. Usually a combination of topical and oral anti-inflammatory and / or immunosuppressant medications is prescribed to treat the condition. Once the episcleritis is in remission, the medications are slowly tapered over a period of several months to minimize the risk of recurrence. In severe cases surgical debulking of the nodules with cryotherapy (freezing procedure) may be necessary to induce remission.

A treatment regimen using oral tetracycline and niacinamide (Vitamin B3) over a period of weeks to months has also been described but the results in causing regression of are variable.

Initial aspect of an eye with NGE

Same eye 3 weeks post anti-inflammatory treatment
